## 1 INTRODUCTION

Groundwater Sciences Corporation (GSC) has prepared this progress report of the results of the 2015 annual groundwater monitoring of the Northern Property Boundary Area (NPBA) groundwater extraction system shutdown at the former York Naval Ordnance Plant (fYNOP or Site) located at 1425 Eden Road, Springettsbury Township, York, Pennsylvania (**Figure 1**). The Site is divided into the East Campus, owned by Harley-Davidson Motor Operations, Inc. (Harley-Davidson), and the West Campus, owned by NP York 58, LLC. The groundwater extraction system at the NPBA, operated since November 1990, has been shut down since June 19, 2013 to monitor the effects on groundwater flow patterns and chemistry during a period of non-pumping. The monitored shutdown test was performed as a component of the Part 2 Supplemental Groundwater Remedial Investigation (Part 2 SRI), and resulted in continued shutdown, annual monitoring and reporting. This second year progress report includes the annual monitoring data for 2015. Results are described in Section 2 and the work plan for 2016 is described in Section 3. References are provided in Section 4.

The rationale and plan for deactivation and evaluation of the NPBA groundwater extraction system are described in Section 8.7.5 of the Supplemental Remedial Investigation Groundwater Report (Part 1) (GSC, 2011) and Section 4.3.4 of the Field Sampling Plan (FSP) for the Part 2 SGWRI (GSC, 2012) and Addendum #6 to the FSP (GSC, 2013). Results of the monitored shutdown test were included in a report titled “Results of NPBA Extraction System and Bldg3 Footer Drain Monitored Shutdown Tests for Part 2 of the Supplemental Groundwater Remedial Investigation” (GSC, 2014). The report was submitted to the United States Environmental Protection Agency (USEPA) and the Pennsylvania Department of Environmental Protection (PADEP) on April 11, 2014 and included recommendations for monitoring of the groundwater in the NPBA area. The USEPA approved the shutdown of active pumping of the NPBA groundwater extraction system and annual monitoring in an email reply to Mr. Stephen Snyder of GSC, dated April 17, 2014.

The approved monitoring plan involves the monitoring and reporting of groundwater levels and chemistry at the NPBA on an annual basis for a period of five years from 27 locations in and north of the NPBA. Monitoring results from six additional on-Site wells located down-gradient of the NPBA (wells MW-3, MW-82, MW-102S&D and MW-103S&D) are included in this 2015 annual

April 2016

NPBA report to track the potential migration of chemicals of concern (COCs) in the down-gradient direction on-Site. After five years of monitoring (i.e. 2018), long-term shutdown of the NPBA groundwater extraction system will be re-evaluated.

*April 2016*

## 2 2015 ANNUAL MONITORING PROGRESS

Second year (2015) monitoring results are discussed in this section, followed by a discussion of the primary concerns (the potential for off-site migration of Site-related COCs). Groundwater locations monitored in 2015 are shown on **Figure 2** and are summarized below:

<b>NPBA and Off-Site Locations</b>				<b>Additional Down-gradient Locations</b>
CW-1	CW-7	MW-18S	MW-143S	MW-3
CW-1A	CW-7A	MW-18D	MW-143D	MW-82
CW-2	MW-9	MW-20S	RW-2	MW-102S
CW-3	MW-11	MW-20M	RW-4 (Folk)	MW-102D
CW-4	MW-12	MW-20D	Tate (S-6)	MW-103S
CW-5	MW-16S	MW-142S		MW-103D
CW-6	MW-16D	MW-142D		

### 2.1 Groundwater Elevations and Gradient

Groundwater elevation measurements at the NPBA were collected on September 2 and 3, 2015 by Leidos Engineering, LLC and GSC personnel as part of the Site-wide water level monitoring event. Elevation measurements collected in 2015, plus elevations from prior to and during the NPBA groundwater extraction system shutdown testing period are listed in **Table 1**. In the 2015 monitoring event, the groundwater elevations, excluding wells under artesian pressure, ranged from a high of 530 feet above mean sea level (amsl) in the northeast to 370 feet amsl in the southwest (**Figure 3**). Wells MW-16D, MW-18S&D exhibit artesian conditions and contain packers to seal the flow of groundwater to the surface. Wells MW-20M&D do not contain packers, but the water elevations are high in these wells suggesting that the groundwater is under pressure at those locations. It should be noted that the water level in the unused residential well RW-2 was measured on September 16, 2015 and the water level in private non-potable well RW-4 (Folk) was measured on September 26, 2015 when the homeowners allowed access. In addition, wells RW-1, RW-3 and the spring Herman (S-7) shown on **Figure 2** are not accessible for monitoring because property owners have denied access to RW-3 and Herman (S-7). As a result of a search of the property and discussion with the current resident, RW-1 is believed to be abandoned.

Groundwater elevation contours of measurements collected on September 2 and 3, 2015 are shown on **Figure 3**. These contours represent the shallow groundwater elevation under natural flow

*April 2016*

conditions (non-pumping conditions) and show a lateral gradient that slopes toward the southwest. As interpreted and under isotropic conditions, groundwater flow is theoretically perpendicular to contours and would indicate that groundwater from a very small portion of the NPBA near wells MW-18D&S may minimally flow off-Site to the west of wells MW-142D&S, but flows back onto the Site west of MW-143D&S. A groundwater flow direction arrow is shown on **Figure 3** illustrating the theoretical groundwater flow path if the aquifer were isotropic. It is noted that the flow path, as drawn, is essentially parallel to the property line. However, factors such as a small change to the groundwater contour orientation, the consideration of anisotropic and heterogeneous aquifer permeability, combined with the lack of water level observation points to the north and west of MW-18 add uncertainty to the flow path interpretation.

Groundwater elevations and potentiometric contours from September 2 and 3, 2015 are shown in the cross section on **Figure 4**. Vertical groundwater gradients can be observed on the figure for nested wells MW-18S&D; MW-20S, I, & D; MW-142S&D; and MW-143S&D. In each of these wells except MW-142S&D, the groundwater elevation of the deeper well is higher than the elevation in the shallower well pair. This indicates that vertical groundwater flow is upward at these well locations under non-pumping conditions. Given this vertically upward flow gradient, dissolved COCs would not migrate deeper into the aquifer under natural (non-pumping) conditions.

Comparing the September 2015 groundwater elevations and potentiometric contours to the September 2013 post-shutdown and October 2014 elevations and contours, there is essentially no change in groundwater flow in the NPBA area.

## 2.2 Groundwater Chemistry

Groundwater sample collection occurred from September 21 through October 6, 2015, coincident with the annual comprehensive well sampling across the Site. Samples were submitted to TestAmerica Pittsburgh for analysis of volatile organic compounds (VOCs) by Method 8260C. Recent chemistry data for the NPBA wells are summarized in **Table 2**. Isoconcentration contours for trichloroethene (TCE), the most common COC at the NPBA, are shown on **Figure 5** for wells screened or open to the top 110 feet below ground surface (bgs). **Figure 5** illustrates that the highest TCE concentrations in 2015 were centered around wells CW-7A and MW-12, and that TCE

concentrations of 5 micrograms per liter ( $\mu\text{g}/\text{L}$ ) or more were interpreted to exist in the groundwater beneath most of the NPBA.

Historical chemistry data are shown on the graphs in **Appendix A**. **Figure 5** (plan view) and **Figure 6** (cross sectional view) show posted TCE and tetrachloroethene (PCE) chemistry data from pre-shutdown and post-shutdown in 2013, annual post-shutdown sampling in 2014, and the second annual post-shutdown sampling in 2015 for these primary COCs. Small changes between the September 2013 post-shutdown, October 2014, and the 2015 annual sampling chemistry are noted at most of the sample locations, with the majority of samples (24 of 26) decreasing or remaining about the same with respect to COCs. Locations that exhibited increases in PCE concentrations compared to the post-shutdown September 2013 concentrations were at former extraction wells CW-5 and CW-7A, where pumping had likely caused dilution while the extraction system was operating. Reference to graphs of time vs. concentration for these two wells in **Appendix A** illustrate the following:

- Prior to system shutdown, detections of PCE in CW-5 showed a declining trend. After pumping ceased, the PCE concentration increased from 2.5 to 7.4  $\mu\text{g}/\text{L}$  in 2013. In 2014, PCE increased to 24  $\mu\text{g}/\text{L}$ , and then dropped to 15  $\mu\text{g}/\text{L}$  in 2015.
- Prior to system shutdown, detections of PCE in CW-7A showed a declining trend. After pumping ceased, the PCE concentration increased from 1.4J to 4.3J  $\mu\text{g}/\text{L}$  in 2013. In 2014, PCE increased to 5.5J  $\mu\text{g}/\text{L}$ , and then to 8.6  $\mu\text{g}/\text{L}$  in 2015. (Note that “J” refers to results that are less than the laboratory’s reporting limit, but greater than or equal to the method detection limit; the concentration is an approximate value).

In addition to the 26 wells listed above for annual monitoring, groundwater chemistry data from MW-3, MW-82, MW-102D&S and MW-103D&S also have been compared to historical data. These wells are located downgradient of the former extraction wells in the NPBA, theoretically receiving groundwater flow from the NPBA. TCE, PCE and cis-1,2-dichloroethene (cis12DCE) concentrations were similar to the historical groundwater data in MW-3, MW-82 and MW-102D&S, while TCE concentrations in MW-103D&S have declined (see graphs in **Appendix A**).

An additional downgradient well, MW-77, was sampled in 2014, but was not sampled in 2015 because it is located in an area of hydrocarbon release and has been part of a separate study.

The following bulleted text is taken from the monitored shutdown report (GSC, 2014), which explains the chemistry trends seen 12 weeks (September 2013) after extraction system shutdown. Added to that text is a brief summary of observations of changes approximately one year later in 2014 (provided in the 2014 annual shutdown report [GSC, 2015]) and two years later in 2015. The added text for 2015 is included in *italics*. Refer to **Figures 5 and 6** for plan view and cross section maps, to **Table 2** for a summary of chemistry data, and to chemistry concentration graphs included in **Appendix A**.

- Five wells are located in the eastern-most extent of the NPBA. MW-20S, M, D and CW-7 and CW-7A are within 20 feet of each other, and sample different depths in the aquifer, from 28 feet – 61 feet (MW-20S) to 153 feet – 165 feet (MW-20D). CW-7 is open to the bedrock aquifer from 61 feet – 150 feet, while CW-7A screens residuum and saprolite (decomposed bedrock maintaining the structural features of the bedrock) from 34 feet – 66 feet bgs. Concentrations of TCE are highest near the surface, and decrease with depth, with groundwater from MW-20S showing the highest concentrations during pumping. MW-20S concentrations dropped after cessation of pumping, suggesting TCE was being pulled through that well by pumping, and potentially indicating the location of higher concentrations of TCE to be to the east of MW-20S. CW-7A concentrations increased after cessation of pumping, indicating portions of the flow drawn in by pumping most likely had been diluting the concentrations. CW-7 TCE concentrations dropped after pumping ceased, indicating pumping of that well was likely drawing mass from the shallow portion of the aquifer.

2014 sample results suggest no significant changes from the description above. Concentrations of TCE in CW-7A decreased to a level closer to the pre-shutdown concentration.

*2015 sample results are similar to the descriptions above with the exception that the PCE concentration in CW-7A increased to a high of 8.6 µg/L.*

- Pumping wells CW-1 and CW-1A are open to a depth of 68 feet – 175 feet and 29 feet – 74 feet, respectively. TCE concentrations in these wells prior to cessation of pumping were nearly the same at 33 and 35 µg/L, respectively. With the pumps off, concentrations in both wells dropped to 9.4 µg/L in CW-1 and 26 µg/L in CW-1A.

One year later, the TCE concentration in CW-1 reduced to 1.8 µg/L, while the TCE concentration in CW-1A remained nearly unchanged (31 µg/L).

*Two years later, the TCE concentration in CW-1 reduced to 1.1 µg/L, while the TCE concentration in CW-1A remained nearly unchanged (28 µg/L).*

- Monitoring well MW-11, which lies west of CW-1 and CW-1A and east of CW-2 showed no change in pre- and post-shutdown TCE concentrations (pre-shutdown = 4.5 µg/L vs. post-shutdown = 4.9 µg/L). The water level in this well is higher than wells on either side of it, and there was no apparent recovery (rise) in water level when the extraction wells were shut down. The lack of response in both chemistry and water level, combined with the higher water level than in adjacent wells indicates that water from well MW-11 is not sufficiently hydraulically connected to the pumped portion of the aquifer or that it is being supported by an artesian condition below the pumping wells (deeper water sourced from the elevated area to the east).

2014 sample results suggest no significant changes from the description above. Well MW-3, located down-gradient of and about 600 feet southwest of MW-11, showed no change in concentrations compared to 2013 data.

*2015 sample results suggest no significant changes from the descriptions above.*

- Pumping well CW-2 and adjacent monitoring well MW-9 decreased in TCE concentrations after cessation of pumping. Since the groundwater flow direction at MW-9 while pumping was toward the northwest, and that flow direction would have changed to southwestward when CW-2 stopped pumping, the change in chemistry probably indicates higher concentrations of TCE in groundwater being pulled from the southeast of MW-9. With the cessation of pumping, the concentration of PCE in CW-2 went from undetected (U) to 3

µg/L. PCE was detected in this well prior to initiation of the extraction system at 2 to 4 µg/L. The reappearance suggests the concentration of PCE was being diluted by pulling groundwater from a greater distance away from CW-2. These pre- and post-shutdown results suggest that PCE is adsorbed onto the aquifer material at a location close to or discretely connected to CW-2.

2014 sample results suggest no significant changes from the description above. CW-2 TCE concentrations increased slightly to a level similar to pre-shutdown conditions.

*2015 sample results suggest no significant changes from the description above; however, the TCE concentration in CW-2 decreased to the lowest level to date (4.9 µg/L).*

- The TCE concentration in off-Site former residential supply well RW-2, located 150 feet northwest of CW-2 rose slightly between pre- (1.2 µg/L) and post- (1.9 µg/L) shutdown sampling, but the change is within its normal range of TCE concentrations during pumping. This well has been below applicable PADEP Medium Specific Concentrations (MSCs) for Residential Used Aquifers with total dissolved solids less than or equal to 2,500 milligrams per liter (mg/L) for all site-related COCs since 2003 and the TCE concentrations have ranged from 1.4 (in 2006) to 3.9 (in 2009) over the last seven years of annual sampling.

2014 sample results suggest no significant changes from the description above. The TCE concentration measured one year later was 3.1 µg/L.

*2015 sample results suggest no significant changes from the description above. The TCE concentration measured in 2015 was 3.8 µg/L. Concentrations of TCE and PCE continue to remain undetected (U) in the other former residential supply well, RW-4 (Folk), currently connected to an outdoor spigot, but not used as a potable supply.*

- TCE and PCE concentrations decreased in pumping well CW-4 after cessation of pumping. Adjacent monitoring well MW-12, southwest of CW-4 more than doubled in TCE and PCE concentrations after pumping stopped. This suggests that higher concentrations of these COCs may be located south or southeast of CW-4 and northeast of MW-12, in a position

that is upgradient from MW-12 under the static post-shutdown groundwater potentiometric surface conditions.

2014 sample results suggest no significant changes from the description above. Concentrations of TCE and PCE continued to drop significantly, while MW-12 levels moderated.

*2015 sample results suggest no significant changes from the description above. Concentrations of TCE and PCE continued to drop in CW-4, while the concentration of PCE in MW-12 slightly increased to 6.4 µg/L (an increase of 1 µg/L above the 2014 value).*

- Pumping well CW-3 and adjacent well pair MW-16S and MW-16D are located near the center of the row of extraction wells along the NPBA. The groundwater chemistry in MW-16S is notable in that it shows the highest concentration of PCE in the NPBA, where TCE is the dominant COC. CW-3 concentrations of TCE increased slightly, with the cessation of pumping, but remained in single digits. A pre-shutdown sample of MW-16S could not be analyzed due to excessive turbidity. However, compared to previous samples collected during pumping, the concentration appears to have reduced significantly under post-shutdown conditions. MW-16D, screened at a depth bgs of 190 feet – 201 feet, is artesian, and groundwater quality is minimally influenced by the COCs in the shallower zones in the immediate vicinity, indicated by PCE concentrations being undetected (U).

2014 sample results suggest no significant changes from the description above.

*In 2015, TCE and PCE both decreased significantly to below 10 µg/L in MW-16S, whereas concentrations in MW-16D have remained consistent. TCE and PCE were undetected (U) in CW-3 in 2015, compared to 1.4J and 0.41J µg/L in 2014. CW-3 also contained 460 µg/L of acetone, a common laboratory contaminant, and there was a laboratory issue with the recovery criteria for TCE and PCE in an associated Matrix Spike / Matrix Spike Duplicate (MS/MSD) sample, suggesting that the data at CW-3 may be suspect.*

- Pumping wells CW-5 and CW-6 are west and down-gradient of the CW-3/MW-16 cluster of wells. After cessation of pumping, TCE and PCE concentrations in CW-6 dropped,

suggesting during pumping this well was pulling COCs sourced some distance away from the pumping well. Since the reduction in PCE concentrations was disproportionately high, CW-6 was probably pulling in groundwater with PCE from the MW-16S area. After cessation of pumping, TCE and PCE concentrations in CW-5 increased slightly.

2014 sample results suggest no significant changes from the description above. After one year, CW-6 concentrations continued to drop, while CW-5 concentrations continued to increase slightly.

*2015 sample results suggest no significant changes from the descriptions above. CW-6 concentrations remained stable with respect to 2013 post-shutdown concentrations, while CW-5 concentrations remained stable compared to 2014.*

- Well pair MW-18S and MW-18D are open from 45 feet – 65 feet and 130 feet – 140 feet bgs, respectively. When sampled in 1988, MW-18S had a relatively low concentration of TCE at 50 µg/L, and MW-18D had no detections of VOCs. At the time, this data was considered an indication of the western limit of the plume. These wells were resampled in 2008, and showed concentrations of TCE exceeding 1,000 µg/L in both wells. It was assumed that VOCs were mobilized by the extraction system and pulled through these wells, suggesting a source to the west of this well pair, with VOCs transported by groundwater being pulled eastward toward CW-5 and the other groundwater extraction system wells. As indicated by time vs. concentration graphs in **Appendix A**, concentrations of VOCs in wells MW-18S and MW-18D have generally declined over the last 4 to 6 years. The pre-shutdown concentration of TCE in MW-18S was 220 µg/L while the post-shutdown concentration was 45 µg/L. The pre-shutdown concentration of TCE in MW-18D was 560 µg/L while the post-shutdown concentration was 42 µg/L. Changes that large suggest the pumping of the extraction wells was pulling VOCs through the MW-18 well pair from a source located west of the well pair.

2014 sample results suggest no significant changes from the description above. Continued reductions of TCE concentrations in MW-18S (5.5 µg/L) and MW-18D (8.1 µg/L) support the opinion regarding the reason for the observed concentration changes. Wells MW-

142S&D and MW-143S&D, located down-gradient of MW-18S&D, continued to exhibit undetected or very low COC concentrations (TCE concentration of 1.9 µg/L at MW-143S).

*2015 sample results suggest no significant changes from the descriptions above, with concentrations slightly higher than in 2014 in wells MW-18D, MW-142S and MW-143S, but lower than the post-shutdown concentrations from 2013. The TCE concentration in MW-18S increased from 5.5 µg/L in 2014 to 11 µg/L in 2015, which is still well below the pre- and post-shutdown concentrations detected in 2013.*

## 2.3 Potential for Off-Site Plume Migration in the NPBA

The two primary potential groundwater flow paths for off-Site plume migration in the NPBA are 1) the potential for migration to the north toward former residential water supply wells and, 2) potential for migration to the west across the Site property line in the vicinity of monitoring well pair MW-18S&D.

### 2.3.1 Potential for Migration to the North

The monitored shutdown report (GSC, 2014) concluded that “natural migration of COCs northward from the NPBA appears to be unlikely” based on the groundwater level contours developed from water levels in wells under non-pumping conditions after shutdown.

Groundwater level contours in plan (**Figure 3**) and profile (**Figure 4**) views are essentially the same as the post-shutdown conditions in 2013 and 2014. No modification to the previous evaluation is warranted by the water level data. Similarly, groundwater chemistry results are consistent with the post-shutdown results, and show no indications of northward migration. Specifically, Site-related COCs continue to remain undetected or detected at concentrations below MSCs in off-Site locations north of the Site at RW-2, RW-4 and Tate (S-6).

### 2.3.2 Potential for Migration to the West

The monitored shutdown report (GSC, 2014) described the existence of a natural (non-pumping) gradient to the south-southwest in the area of MW-18S&D. This gradient is essentially parallel to the Site property line with groundwater west of the property likely flowing back onto the Site west

of the well pair MW-143S&D. The gradient from the September 2015 water levels in this area is consistent with that previous condition.

Groundwater chemistry in down-gradient wells MW-142S&D, MW-143S&D, MW-82 and MW-102S&D two years after shutdown is essentially unchanged, and TCE and PCE concentrations in downgradient wells MW-103S&D have decreased.

*April 2016*

### 3 SUMMARY

Groundwater levels and chemical analyses from the September 2015 annual monitoring of the NPBA area indicate stable (essentially unchanged) conditions from the initial post-shutdown conditions.

The work plan for 2016 is to continue the monitoring of the NPBA groundwater extraction system shutdown, with annual collection of water level measurements and groundwater samples for analysis of VOCs. No changes to the plan are recommended. The annual groundwater level and sampling will coincide with the larger-scope 2016 comprehensive event which is planned for late summer or early fall. The 2016 water level data chemistry data will be analyzed and a progress report will be prepared during the first quarter of 2017. Analysis of the chemistry data will also include wells MW-3, MW-82, MW-102D&S and MW-103D&S located downgradient from the NPBA. The plan is to continue annual monitoring for three more years for a total of five years and then evaluate the possibility of decommissioning the NPBA groundwater extraction system. However, if data indicate migration off-Site of elevated concentrations of COCs, the operational status of the groundwater extraction system will be evaluated sooner.

ANSWER

 GROUNDWATER SCIENCES CORPORATION

Digitized by srujanika@gmail.com

## **Appendix A**

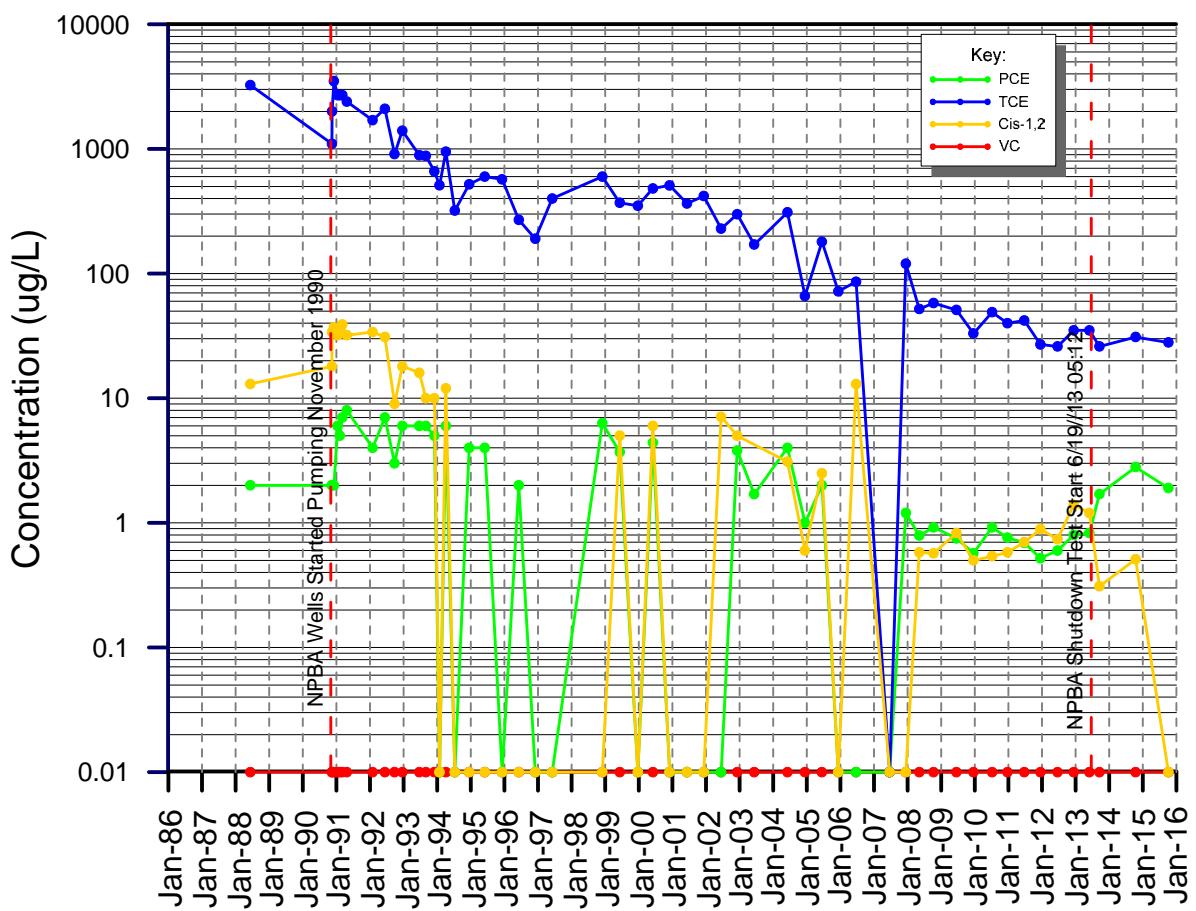

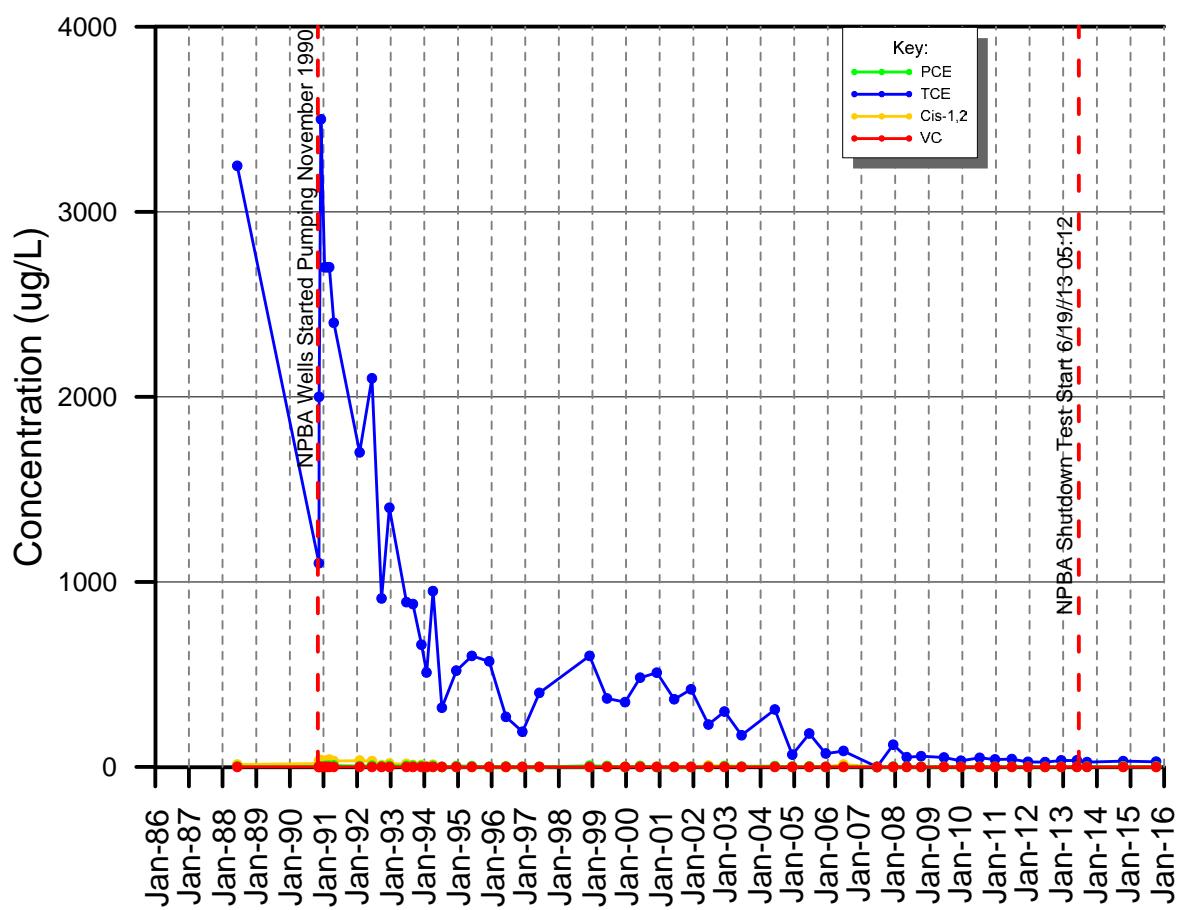

*Undetected laboratory results are represented on the semi-log graphs as a concentration of 0.01 µg/L, regardless of method detection limit or laboratory reporting limit. “J” qualified (estimated) results were plotted as actual values.*
